# Background

---

- Motivation
  - Ammonia ( $\text{NH}_3$ ) combustion does not generate  $\text{CO}_2$
  - Hydrogen carrier, renewable, etc.
- Challenges
  - Ammonia is very difficult to ignite
    - Octane number  $\sim 130$
    - Autoignition  $T \sim 651 \text{ }^\circ\text{C}$  (gasoline:  $440 \text{ }^\circ\text{C}$ ; diesel:  $225 \text{ }^\circ\text{C}$ )
  - Ammonia flame temperature is lower than diesel flame  $T$
  - Erosive to some materials
  - Ammonia emissions can be harmful
  - Potential high  $\text{NO}_x$  emissions due to fuel-bound nitrogen

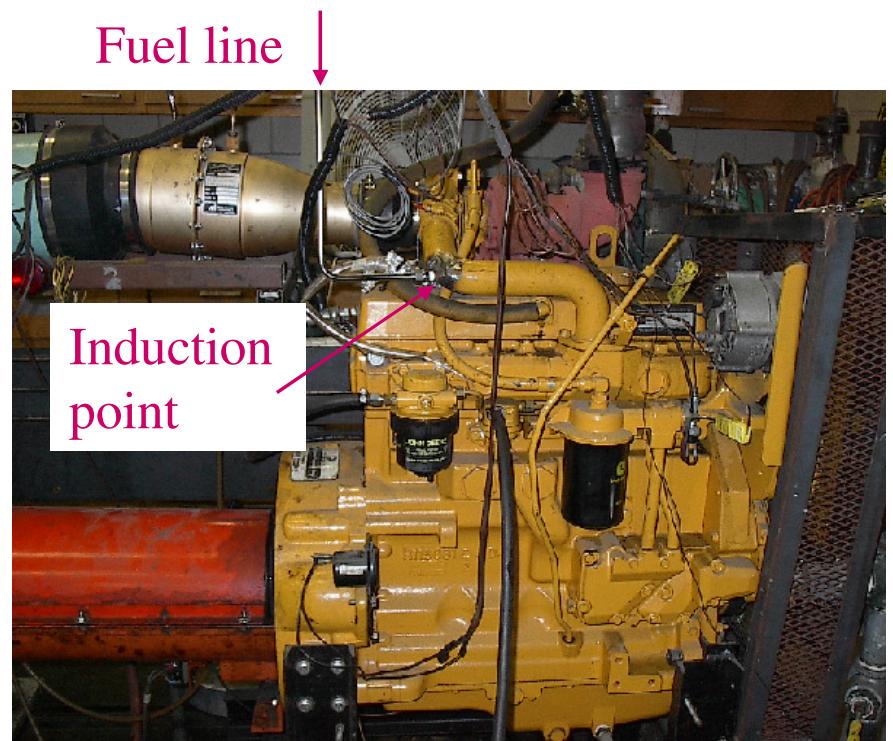

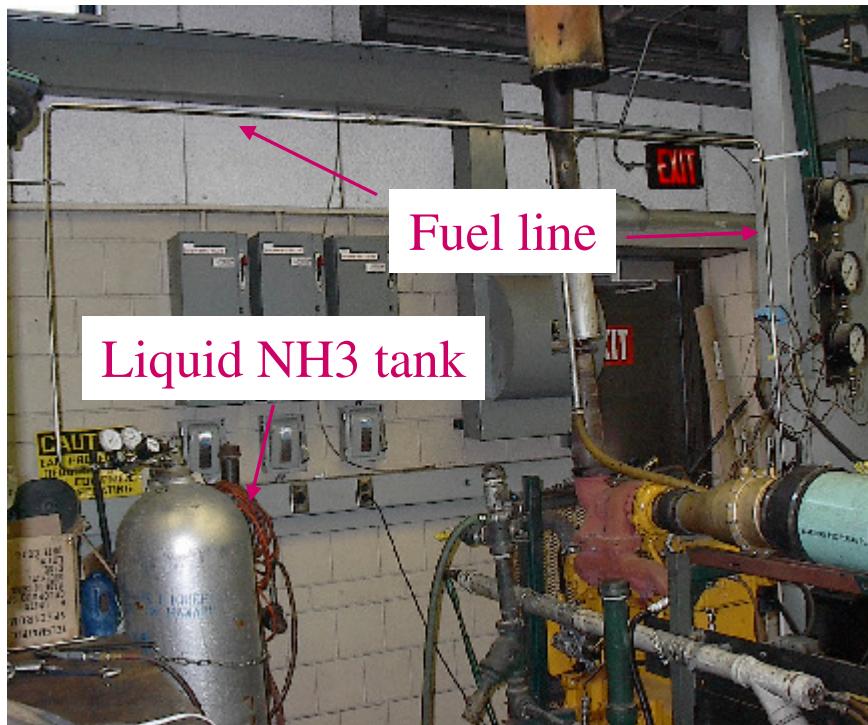

# Approach

- Introduce ammonia to the intake manifold
- Create premixed ammonia/air mixture in the cylinder
- Inject diesel (or biodiesel) to initiate combustion
  - Without modifying the existing diesel injection system

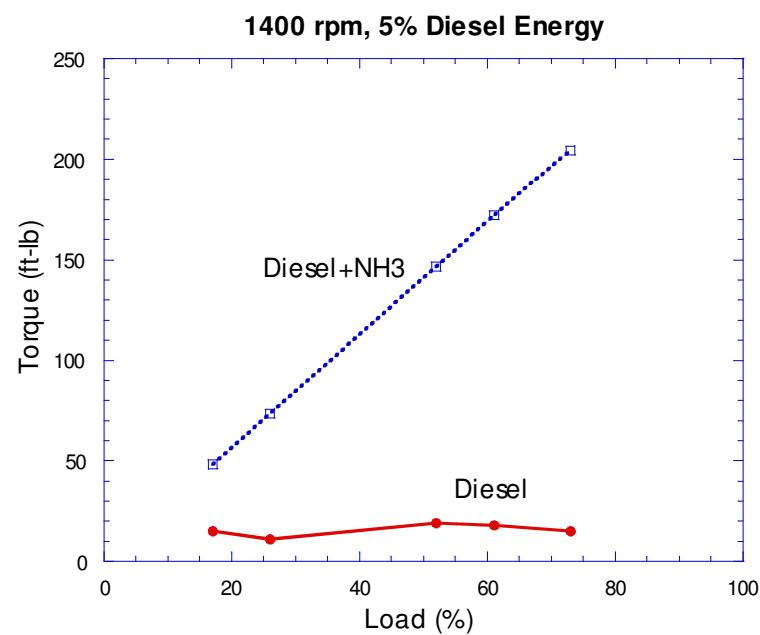

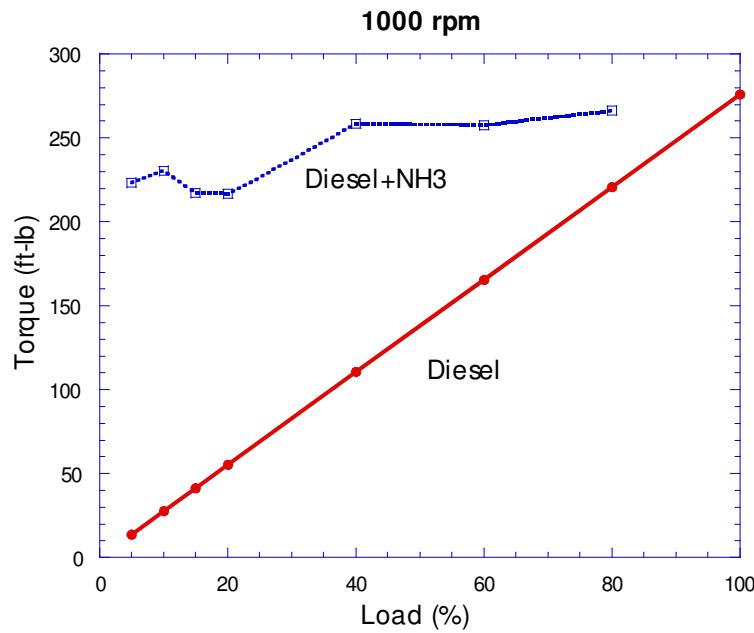

# Ammonia Fueling System

- Fuel system
  - Vapor ammonia introduced into the intake duct – after turbo, before manifold

# Review – Previous Results

- Demonstrated ammonia combustion with D2 and B100
  1. Constant ammonia flow rate → constant torque increase
  2. Varied diesel and ammonia flow rates to maintain constant torque
  3. Used 5% diesel, varied ammonia flow rate for variable torque

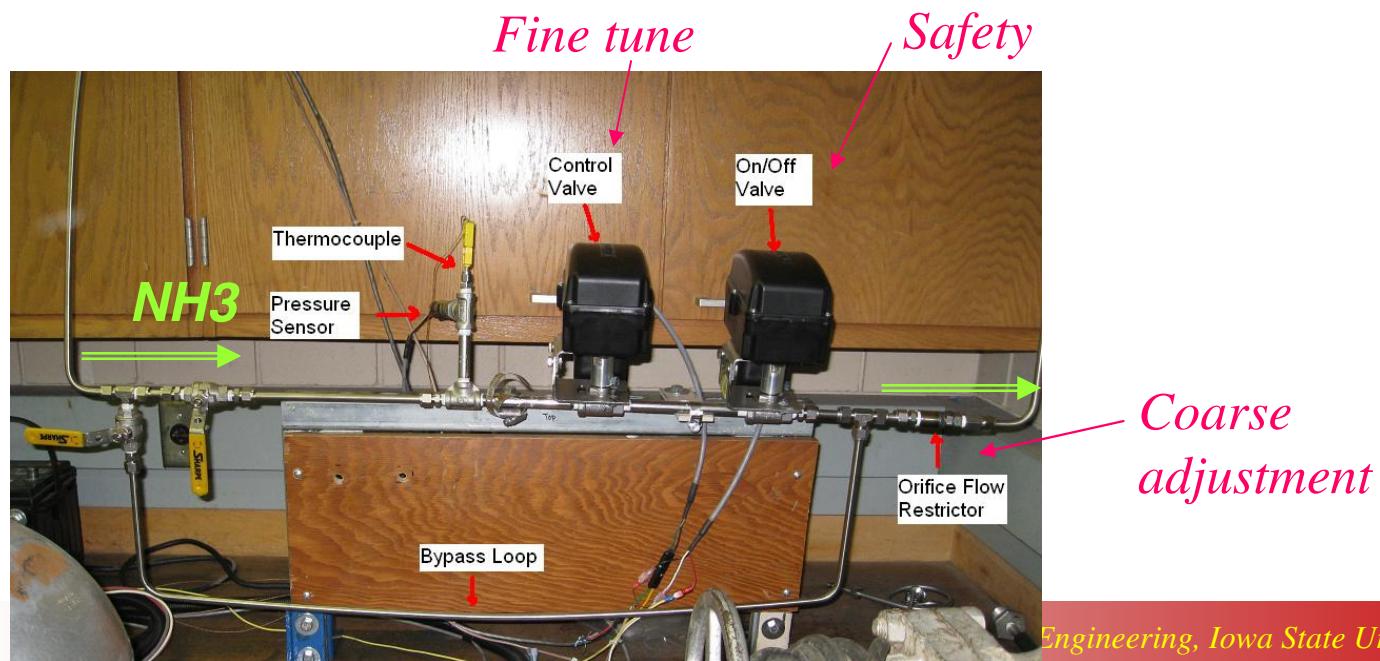

# Present Results

---

- Ammonia flow rate control
- Gaseous and particulate emissions measurements
- Exhaust ammonia measurements
- Ammonia combustion efficiency
- Engine thermal efficiency analysis

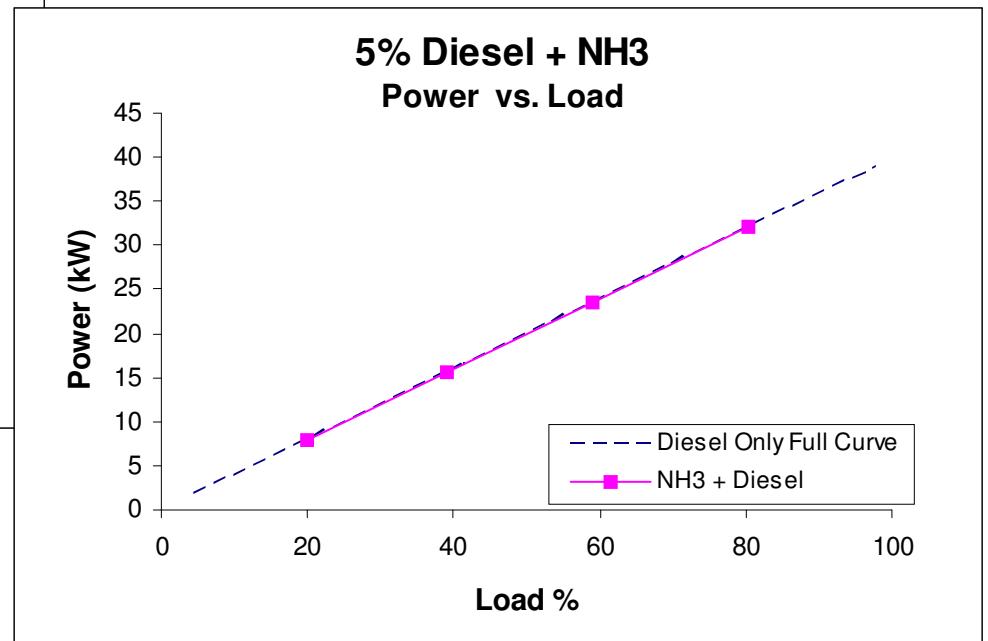

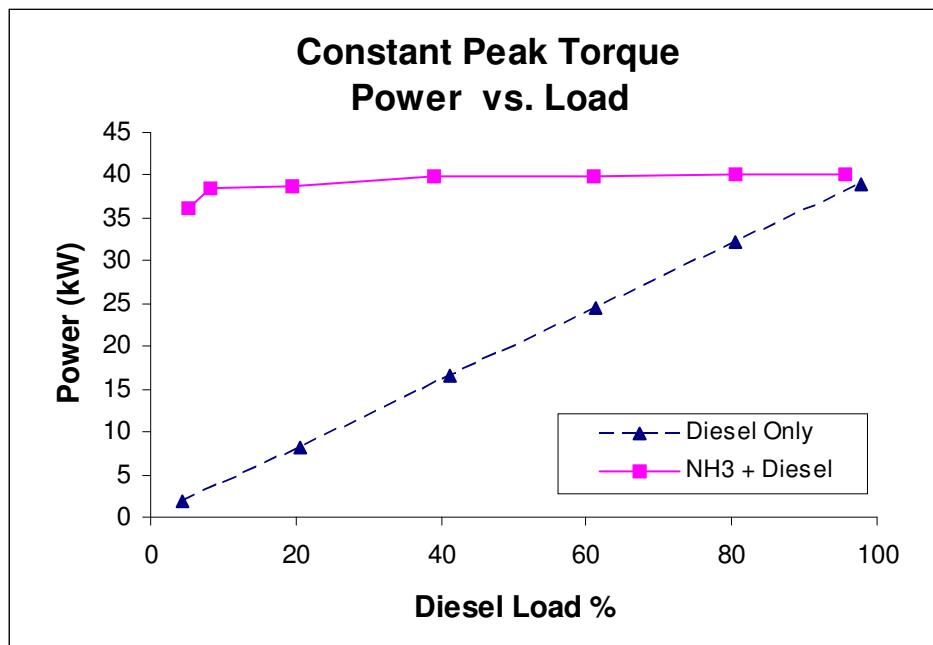

# Ammonia Flow Rate Control

- Issues:
  - Materials – require stainless steel, carbon steel
  - High pressure, high flow rate (as compared to other lab uses)
    - 0.5 lb/min for 1000 rpm, full load, 95% energy replacement
  - Ag industrial application – regulating liquid ammonia at higher flow rates
- Developed control mechanism

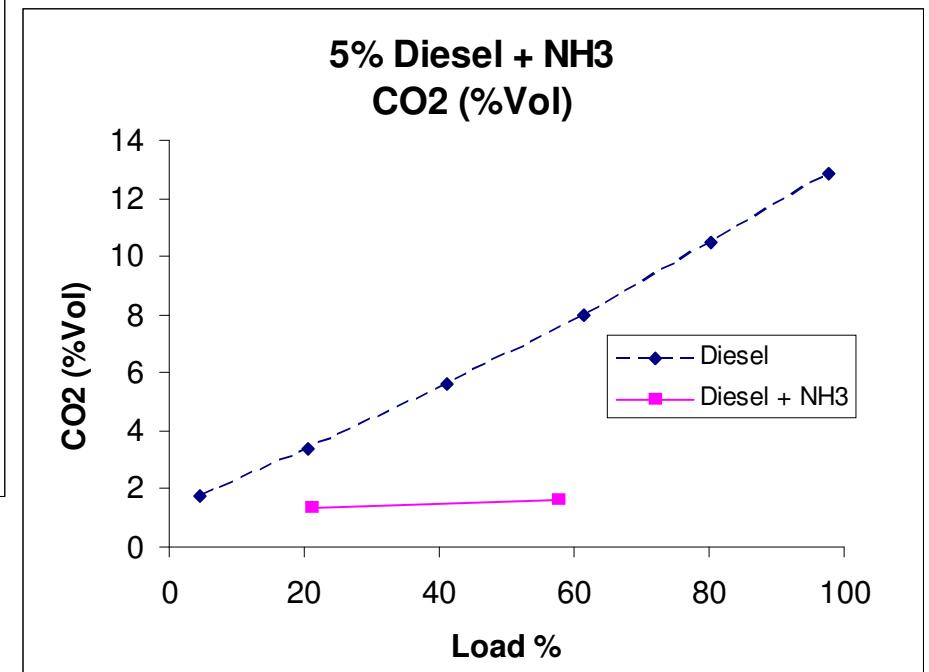

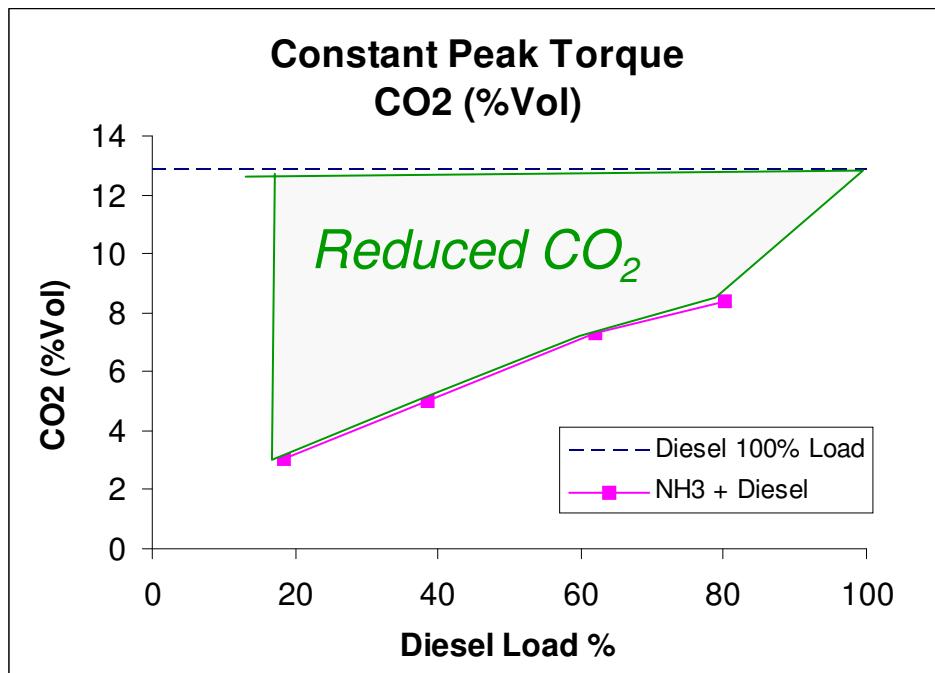

# Engine Test Results

- Obtained stable engine power output

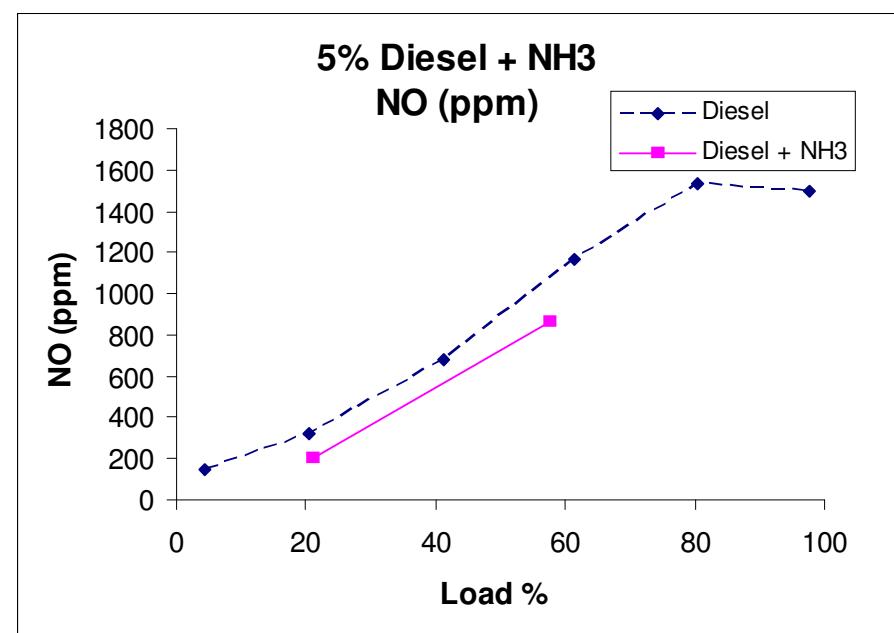

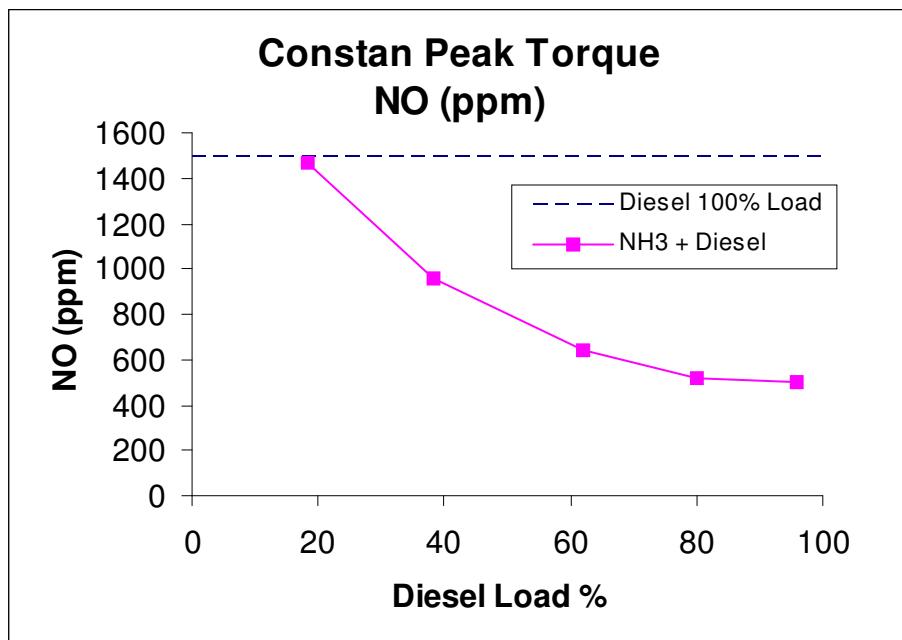

# CO<sub>2</sub> Emissions

- Always much lower than diesel values

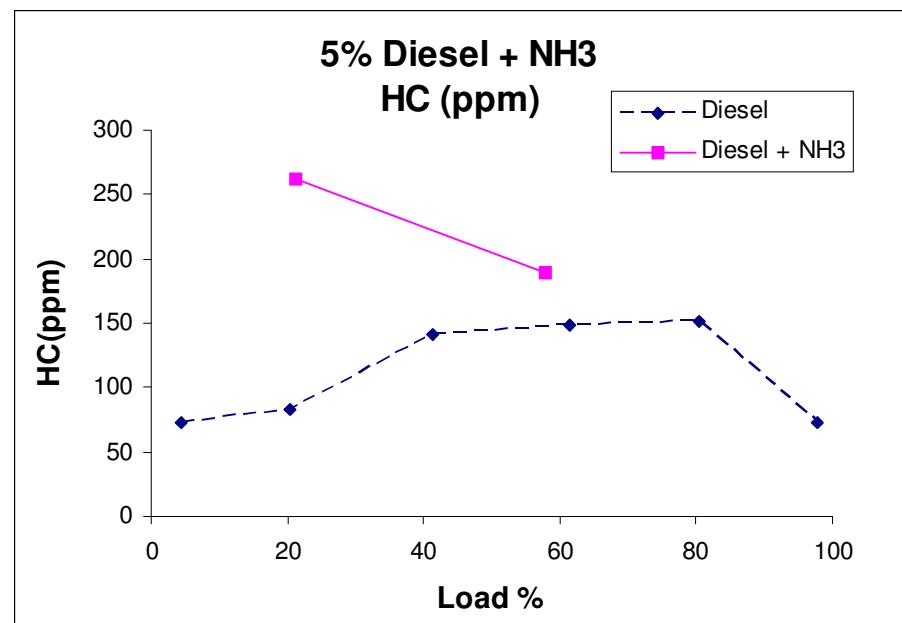

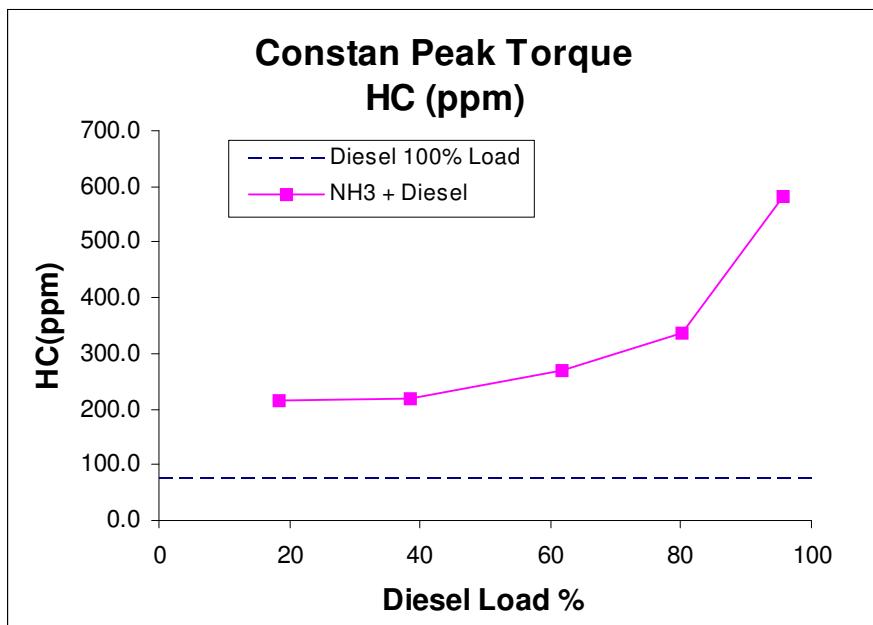

# NO Emissions

- Ammonia can poison NO converter
  - Replace material from COM-03 to COM-GC3
  - This “glassy carbon” is resistant to such poisoning
- Thermal NO & fuel-bound NO

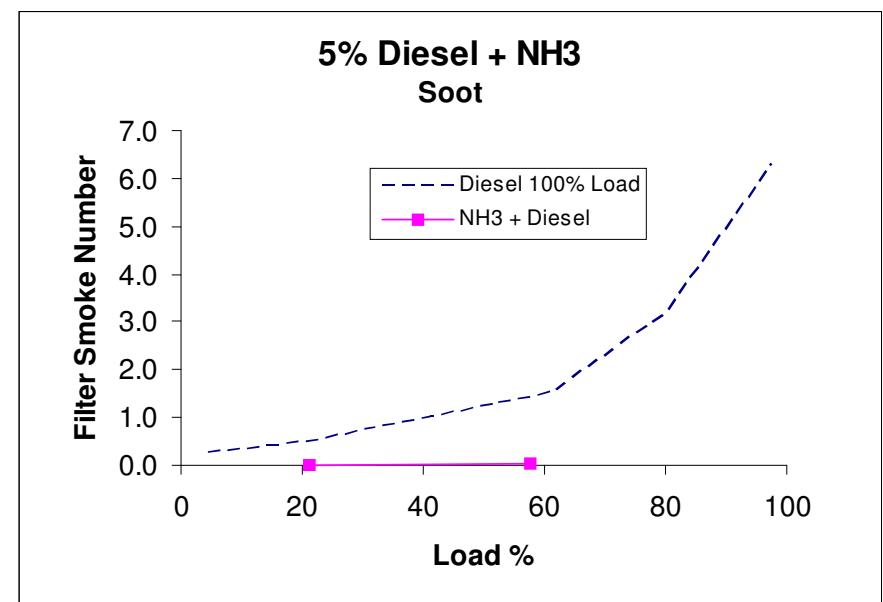

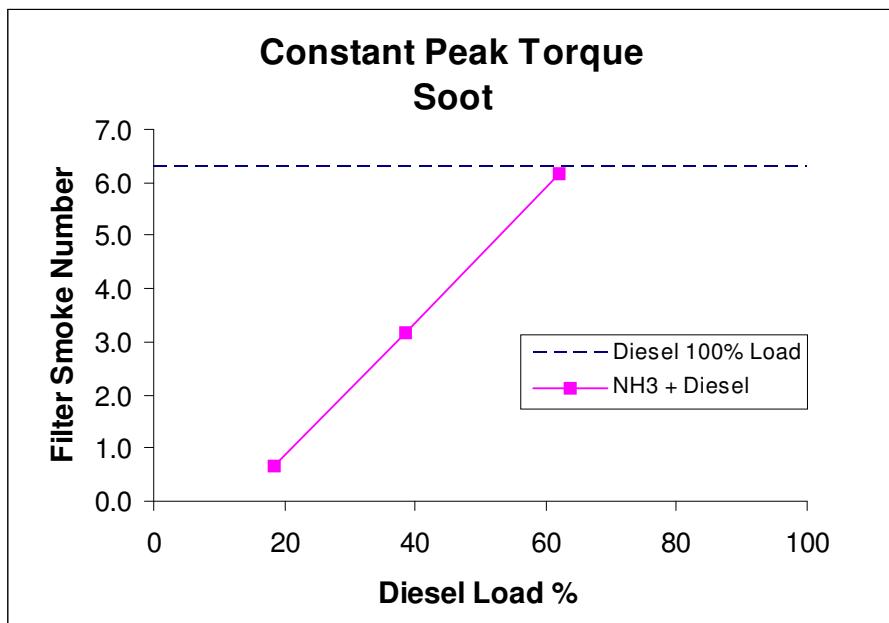

# Hydrocarbon Emissions

- Hydrocarbons are higher
  - Due possibly to incomplete combustion of diesel fuel caused by lower flame temperature of ammonia

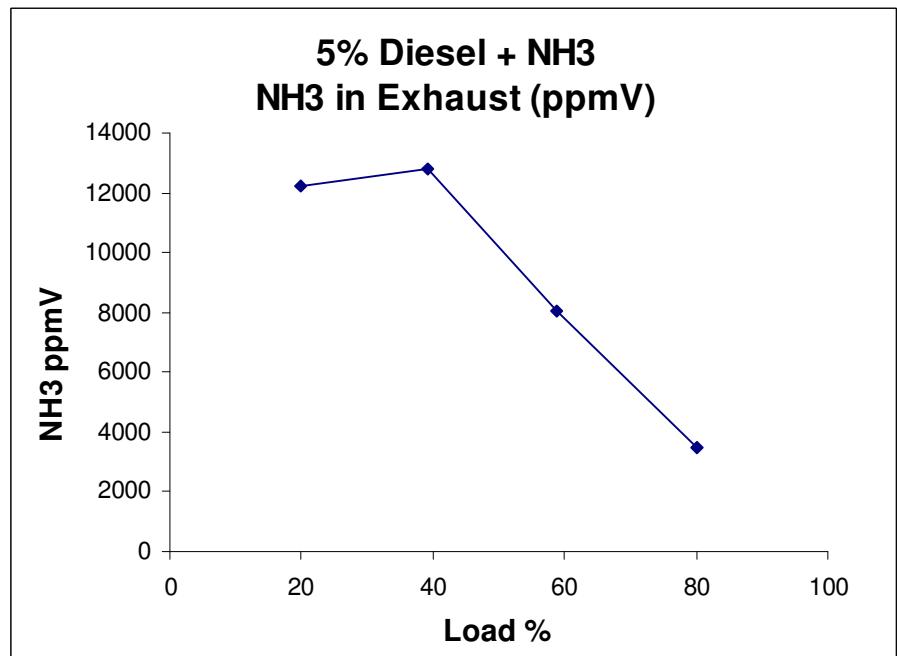

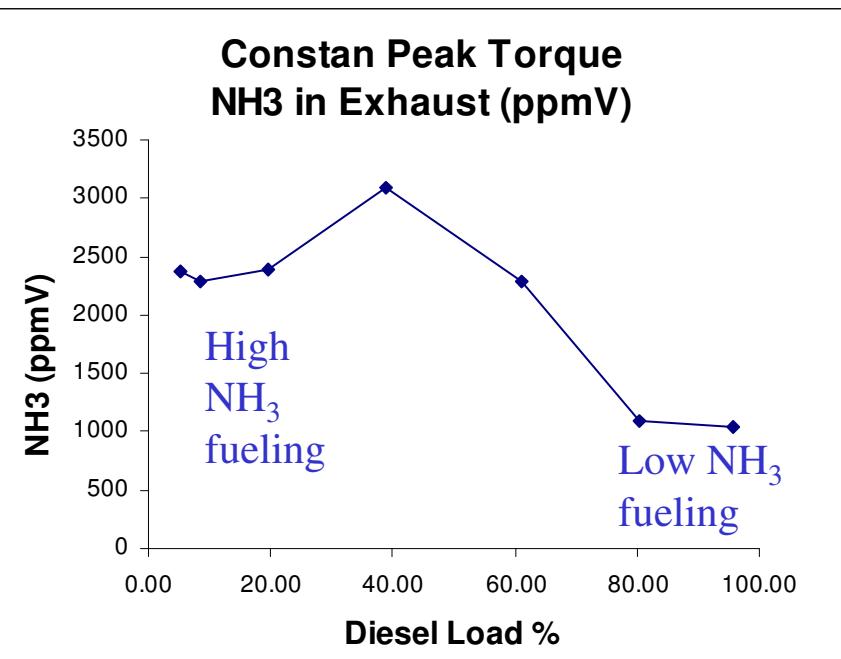

# Soot Emissions

- Soot emissions vary depending on fueling rates

# $\text{NH}_3$ Exhaust Concentrations

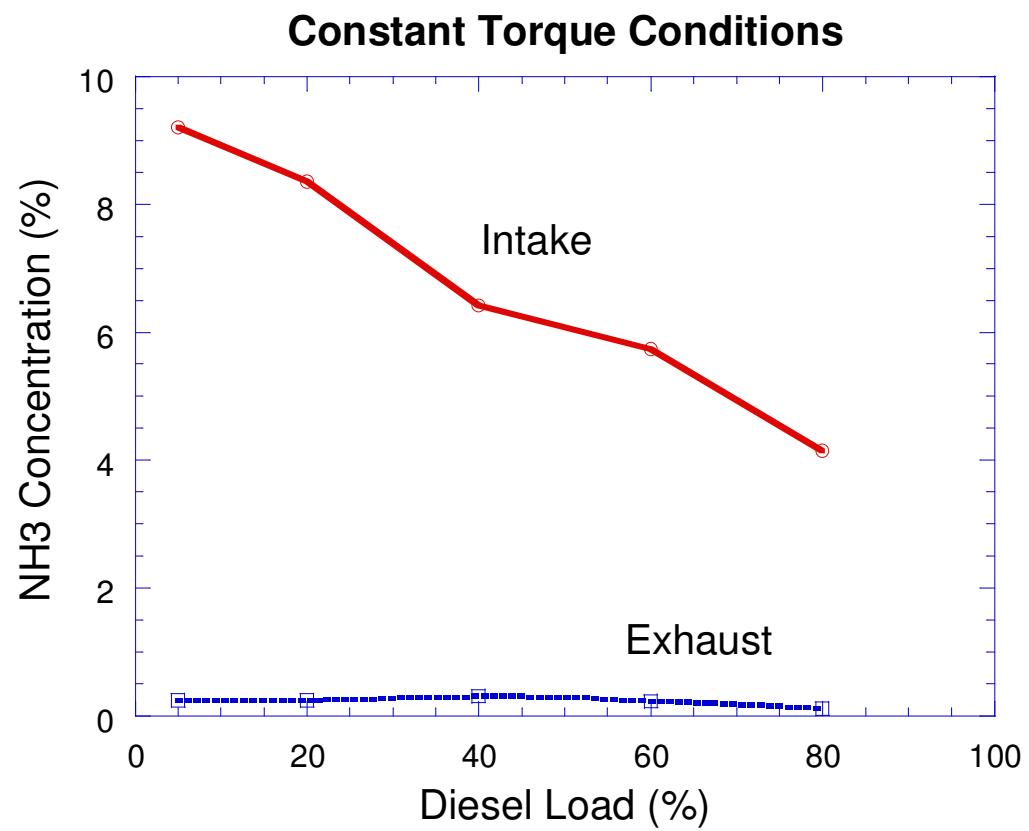

- Concentrations vary depending on  $\text{NH}_3$  fueling rate
- Further study is required to reduce  $\text{NH}_3$  emissions.

This strategy might not be feasible  
– not sufficient diesel energy to  
initiate combustion.

# $\text{NH}_3$ Intake/Exhaust Concentration

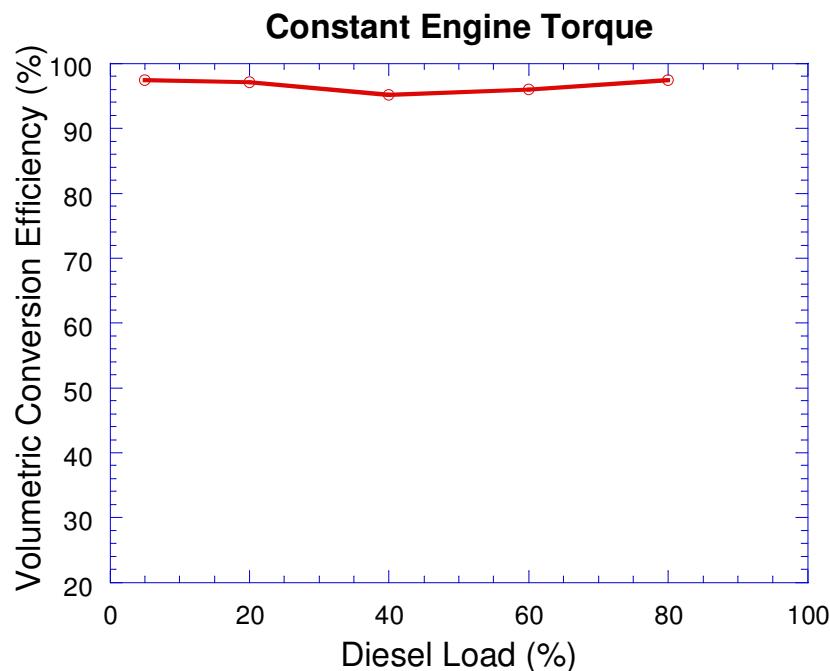

- Constant torque conditions

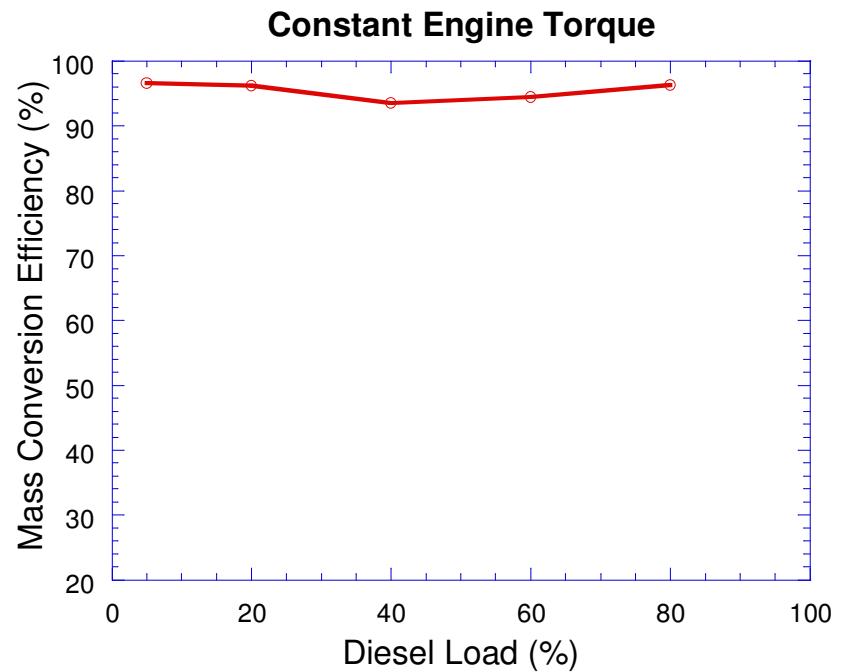

# NH<sub>3</sub> Combustion Efficiency

- Constant engine torque conditions

## Volume conversion efficiency

## Mass conversion efficiency

# Summary

---

- Reasonable fuel economy between 40~60% diesel fueling
- Ammonia combustion efficiency ~ 95%
- Ammonia emissions: 1000 ~ 3000 ppm under the specific conditions tested
- Future work –
  - Improve combustion efficiency of ammonia
  - Ammonia flow rate control depending on engine loads
  - Optimize diesel/ammonia dual-fuel system
  - Ammonia removal in exhaust
